Pedestrian Instance Segmentation

The Core Objective: 70%+ AP50

My project centers on achieving a high accuracy threshold on the **PennFudanPedestrian dataset**.

- **Why Streamlit failed my execution:** Streamlit's "hot-reloading" (re-running the whole script for every slider move) was computationally expensive for my **Mask R-CNN** architecture. This often led to the "Connection failed with status 503" because the tunnel couldn't keep up with the constant re-loading of the model weights into the GPU.
- **Why Gradio won my execution:** Gradio keeps the model loaded in memory and only executes the inference function when I click on **Submit.** This efficiency is what I allows to demonstrate the expected criteria (the 70% accuracy) without the UI crashing.

Technical Execution Comparison

Based on your work with Mask R-CNN and planned experiments with YOLACT and SOLO, here is how the technical pieces fit together:

Execution Phase	Your Specific Action	Technical Benefit
Data Acquisition	Heavy augmentation (flips, scales, brightness).	Prevents overfitting on the small PennFudan dataset to help hit that 70% AP50.
Model Tuning	Adjusting RPN NMS thresholds (0.5 vs 0.7) and ROI Align sizes (14 vs 28).	Optimizes the precision of the bounding boxes and masks for the "Tracking" part of the rubric.
UI Deployment	Switched from localtunnel/Streamlit to native Gradio sharing.	Eliminated the "File does not exist" error and the need for endpoint IP passwords.

Architecture & Performance (The 70%+ AP50 Goal)

My project focuses on fine-tuning a **Mask R-CNN** model on the **PennFudanPedestrian dataset**.

- **The Execution:** You trained the model for **50 epochs** using a custom PyTorch loop.
- **The Success Insight:** By using heavy data augmentation and tuning parameters like the **RPN NMS threshold** and **ROI Align output size**,I optimized the model to hit the required accuracy targets.
- **Technical Reason for Gradio:** Mask R-CNN is a "heavy" model. Every time I adjusted a slider in Streamlit, the tool attempted to re-run the entire script, often causing the **503 Tunnel Error** because the connection timed out during the model reload. Gradio, however, keeps the model "warm" in memory, allowing for instant inference without crashing the connection.

Why Gradio fits my Rubric point

The rubric specifically asks for **per-instance statistics** and **tracking insight**.

- **Streamlit's hurdle:** It was difficult to display real-time data tables alongside the image without the tunnel dropping.
- **Gradio's success:** You successfully implemented a Textbox output that prints the specific ID and confidence score for every detected pedestrian. This gives the audience a clear success Insight that the model isn't just seeing a crowd, but individual instances.

Submit

Conclusion

In this project, I successfully implemented a **Pedestrian Instance Segmentation** system using **Mask R-CNN** on the **PennFudanPedestrian dataset**, achieving the target performance of **70%.**.While the technical implementation focused on fine-tuning for **50 epochs** and optimizing parameters like **RPN NMS thresholds** and **ROI Align output sizes**, the most significant challenge was the deployment of a functional user interface in the Google Colab environment.

Initially, I attempted a **Streamlit** implementation, which faced persistent hurdles due to **localtunnel** connectivity issues, "503 Tunnel Unavailable" errors, and the rigid file-based execution requirements of the framework in a cloud notebook. By pivoting to **Gradio**, I leveraged a more memory-efficient and stable networking strategy that provided a seamless shareable experience for peer review without the need for manual IP password entry. This transition allowed for a robust demonstration of **per-instance tracking statistics**, satisfying the final requirements of the project grading rubric.
